Leaf Miners—Botanical Control Formulations

Leaf miners are members of several different insect orders. They are primarily either flies (Diptera) or moths (Lepidoptera) but are sometimes beetles (Coleoptera). Agromyzidae is a fly and is very commonly the culprit of agricultural damages. The life cycle can be completed several times a year in warmer regions and fewer in northern areas. In the fall, the remaining pupae in the soil overwinter and then emerge as adults when it warms up in the spring. These mate and the females lay eggs in host plants where the larvae tunnel in between the leaf surfaces, feeding on chlorophyll-laden cells, leaving tell-tale trails in their wake. These pests slowly reduce the plant's ability to photosynthesize and also provide entry points for disease, further weakening crops. By using certain botanical formulations, leaf miners can be either killed or deterred from laying eggs.

Quassia

Quassia bark powder was more effective than malathion in tests conducted in Guyana. For the study, researchers boiled 45g of Quassia wood chips in water for 30 minutes. This mixture was then topped up to 1 liter after straining. Adding a few drops of dish soap will help the spray adhere to the leaves and completely cover desired plants with the solution (Pluke et al., 1999). Quassia is also effective against aphids, sawflies, diamondback moths, some beetles, and mealybugs (Wateau et al., 2010).

Chili Peppers

Peppers also have been shown to reduce leaf miner populations. Depending on the strength of the peppers, you can add 150g of dried, powdered peppers to a liter of water, allow the solution to soak overnight, and then add 2 more liters of water. A few drops of dish soap can be added to help make the capsaicin, the actively 'hot' ingredient in pepper, adhere to the plants. CAUTION: making your own pepper powder must be done in a well-ventilated area with breathing and eye protection. DO NOT allow the pepper or solution to contact your skin (Pluke et al., 1999). Others have used various pepper extract-based products to drive away adult leaf miners.

Neem

Neem Azal T/S, an azadirachtin-based product, at 40 ml per liter of water was found to be as effective as or more effective than chemical pesticides in controlling leaf miners on both bean and tomato plants. Neem didn't persist for very long and required reapplication, but was found to work both systemically and penetrated the leaf surface to act as an insect growth regulator (Yildirim and Civelek, 2010). Another study found that neem seed extract/water solutions at concentrations of 0.1, 0.05, and 0.025 were effective in killing both eggs and larvae of leaf miners on lima beans (Webb et al., 1983). Neem was also injected into conifers (Helson et al., 2001) and birch trees (Marion et al., 1990) to successfully act as a systemic pesticide against leaf miners and significantly reduce leaf miner infestation. Injection solutions were at a slightly higher concentration than foliar sprays but still very low; both 1.5% and 3% solutions were effective.

Walnut Leaves

Walnut leaf extract, principally Juglone, was found to reduce leaf miner damage to less than 3% but requires weekly application to maintain efficacy. In one study, researchers produced a tincture by extracting the phytochemicals from powdered leaves with ethyl alcohol. They used 50 g of material and 250 ml of pure ethanol in a Soxhlet apparatus (Rizvi et al., 2015). This can be done at home with 50% or higher clear alcohol such as vodka. Fill a quart-sized mason jar with dried walnut or black walnut leaves, cover with alcohol, and let sit for eight weeks. After this time, the liquid should be poured through cheesecloth into a dark-colored, glass storage container. The leaves also should be squeezed through cheesecloth into the container. This extract should be mixed with water in a spray bottle and applied weekly to discourage leaf miners from depositing eggs on plants. As with all botanicals, strength of the solution will depend on many factors so when testing a newly made product start off with a weaker solution, less than 5%, and work incrementally up until the desired results are achieved without causing harm to the treated plant. This will be relative and very case specific due to potency at an individual plant level. This is due to differences in soil, nutrition status of the plant, the weather and UV intensity. Phytotoxicity usually appears in the form of curling leaves, drying leaves, or dead leaf edges. This process will also work with almond leaves.

The screenshot shows the ATTRA Sustainable Agriculture website. At the top, there's a navigation bar with links for Home, Contact, Events, News, Funding, Tutorials, Webinars/Videos, Publications, Internships, Español, About, Donate, and Search. There are also buttons for 'SUBSCRIBER SIGN IN' and 'SUBSCRIBE TO ATTRA'. Below the navigation, a search bar says 'Search This Site' with a magnifying glass icon and a 'Search' button. To the right, it says 'Call our experts: 1-800-346-9140'. On the left, there's a sidebar with links for 'Search This Site', 'What Is Sustainable Agriculture?', 'Master Publication List', 'Search Our Databases', 'Urban Agriculture', 'Energy Alternatives', 'Beginning Farmer', 'Field Crops', 'Horticultural Crops', 'Livestock & Pasture', 'Local Food Systems', 'Marketing, Business & Risk Management', 'Organic Farming', 'Pest Management', 'Soils & Compost', 'Water Management', 'Other Resources', and 'Home Page'. A 'click here to DONATE' button with a stylized leaf logo is also in the sidebar. The main content area has a breadcrumb trail: Home > Pest Management > Biorationals: Ecological Pest Management Database. It features a heading 'Biorationals: Ecological Pest Management Database' by Rex Dufour, NCAT Agriculture Specialist. Below this is a search form with fields for 'Select a Pest Type', 'Select a Pest Name', 'Active Ingredient or Beneficial Organism', and 'Pesticide Trade Name', along with an 'OR' operator and a 'Submit Search' button. A 'Reset Search' button is also present. A note below the search form states: 'The database notes which materials are listed by OMRI (Organic Materials Review Institute). Because OMRI listings are frequently updated, organic growers should always check with their certifiers prior to applying any materials to their crops or livestock.' At the bottom, there's a section about what biorationals are and two icons with descriptions: 'microbial pesticides: formulations of viruses, bacteria, fungi, or nematodes that have low non-target impacts;' and 'pesticides derived from plants that have low non-target impacts and degrade into non-toxic components; and/or'. Finally, a link at the bottom reads: 'For additional information please see the **ATTRA Ecological Pest Management Database** and the ATTRA Publication: **Companion Plants and Botanical Pesticides**'.
